Introduction to Emergency Ultrasound

Tom Ashar, MD*

*Director of Emergency Ultrasound, Department of Emergency Medicine, Newark Beth Israel Medical Center, New York

Abstract:

Emergency ultrasound is a rapidly evolving technology. This article, the first in a series, discusses the unique role of emergency bedside ultrasound. Emergency ultrasound applications and limitations are outlined, as well as educational and administrative requirements.

MeSH Words: emergency ultrasound, residency training, education

Introduction to Emergency Ultrasound

Emergency ultrasound has arrived. Initially a technology utilized in the 1980’s for the evaluation of the trauma patient (the FAST exam)¹²⁄₃ ultrasound in the hands of emergency physicians has rapidly expanded to include the imaging of almost every imaginable body part for a variety of complaints.

This article, the first in a series, will focus on the role of emergency ultrasound as it is practiced today in the United States. Future issues will describe specific applications of emergency ultrasound, both basic and advanced. The focus will be practical information for the practitioner to utilize at the bedside, as well as providing relevant supporting literature.

What is Emergency Ultrasound?

The goal of emergency ultrasound is to answer a focused clinical question in a timely manner. Unlike radiologists and sonographers, emergency physicians do not seek to perform a comprehensive and time consuming evaluation of an organ or body system. Rather, ultrasound as utilized in emergency departments in the United States is an extension of the physical exam – a diagnostic and procedural aide.

Whereas a right upper quadrant (RUQ) ultrasound performed in the radiology suite would evaluate the gall bladder, the liver, the pancreas and other RUQ structures, that performed in the emergency department (ED) is distilled to the relevant clinical dichotomy: Does
Table 1. Basic 6 Applications

<table>
<thead>
<tr>
<th>Application</th>
<th>Focused Clinical Question</th>
<th>Sonographic Finding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cardiac</td>
<td>Is there Cardiac Motion? Is there a pericardial effusion?</td>
<td>Recognize cardiac motion. Identify pericardial fluid.</td>
</tr>
<tr>
<td>Biliary</td>
<td>Is there acute cholecystitis?</td>
<td>Identify GB and GB wall thickness, presence of gallstones, sonographic Murphy’s sign *, common bile duct (CBD) dilatation.</td>
</tr>
<tr>
<td>Renal</td>
<td>Is there hydronephrosis?</td>
<td>Recognize hydronephrosis (dilation of renal pelvis)</td>
</tr>
<tr>
<td>Abdominal Aorta</td>
<td>Is the abdominal aorta enlarged?</td>
<td>Measure abdominal aorta from diaphragm to bifurcation.</td>
</tr>
<tr>
<td>Intrauterine Pregnancy</td>
<td>Is there a live intrauterine pregnancy?</td>
<td>Identify a yolk sac or a fetal pole. Document fetal heart if present.</td>
</tr>
<tr>
<td>Trauma</td>
<td>Is there hemoperitoneum? Is there a hemopericardium?</td>
<td>Anechoic (black) fluid stripe in hepatorenal / splenorenal space or pelvis. Identify pericardial fluid (see above)</td>
</tr>
</tbody>
</table>

*Sonographic Murphy’s Sign – gallbladder tenderness under direct pressure of ultrasound transducer.

The patient have acute cholecystitis? Although with increased operator experience other pathology may be identified, it is the ability to answer an important clinical question in a few minutes spent at the bedside that is the hallmark of emergency ultrasound.

The second feature that differentiates ultrasound performed by emergency physicians is our role in interpreting the clinical relevance of the studies performed. While both the emergency physician and ultrasound technician can identify hydronephrosis of the left kidney, only the emergency physician determines if that finding adequately explains the patient’s clinical presentation or whether further work-up is warranted.

Advantages of Emergency Ultrasound

In general, the advantages of emergency ultrasound include the lack of ionizing radiation, real-time imaging and the fact that it is non-invasive.

Some specific advantages to ultrasound as performed by emergency physicians are as follows:

- Rapidly evaluates a number of critical clinical scenarios from acute shortness of breath to the patient with unexplained shock. 4,5,6,7,8
- Ease of use: multiple investigators have shown that, with only minimal training, emergency physicians can perform many of the required ultrasound examinations9,10,11.
- Performed at the bedside: the unstable patient does not have to leave the emergency department during the critical period of initial evaluation.
- Save time and money by decreasing emergency department length-of-stay (LOS) and other costly imaging for a variety of diagnoses from threatened abortion12,13,14 to renal colic15,16,17,18.

Applications of Emergency Ultrasound

The clinical applications of emergency ultrasound are continually developing. While the practitioner new to ultrasound may focus on
### Table 2. Advanced Applications

<table>

<td>Cellulitis / Abscess</td>
<td>presence of fluid collection in evaluation if soft tissue infections.</td>
</tr>
<tr>
<td>Fracture reduction</td>
<td>proper skeletal alignment after manipulation</td>
</tr>
<tr>
<td>Bladder evaluation</td>
<td>Estimate bladder volume. Localize ideal site for bladder aspiration.</td>
</tr>
</tbody>
</table>

Identifying hemoperitoneum in the trauma patient, studies show that more experienced emergency physicians are performing bedside cardiac echocardiograms with accuracies approaching that of cardiologists. The American College of Emergency Physicians (ACEP), in guidelines published in 2001, classified emergency ultrasound into what has come to be known in the United States as the ‘Basic 6’ Applications, ‘Advanced Applications’, and ‘Procedural Applications’. The accepted ‘Basic 6’ applications are:

1. Identify intra-abdominal or pericardial fluid in trauma.
2. Identify cardiac standstill / asystole.
3. Identify cholecystitis.
4. Identify an abdominal aortic aneurysm.
5. Identify hydronephrosis.
6. Identify an intra-uterine pregnancy.

The American College of Emergency Physicians (ACEP), in guidelines published in 2001, classified emergency ultrasound into what has come to be known in the United States as the ‘Basic 6’ Applications, ‘Advanced Applications’, and ‘Procedural Applications’. (see attached tables). The accepted ‘Basic 6’ applications are:

1. Identify intra-abdominal or pericardial fluid in trauma.
2. Identify cardiac standstill / asystole.
3. Identify cholecystitis.
4. Identify an abdominal aortic aneurysm.
5. Identify hydronephrosis.
6. Identify an intra-uterine pregnancy.
Case Scenarios in Emergency Ultrasound

Case I

**Case History:** 29 year-old female is brought to the ED after motor vehicle collision. Vital signs significant for HR = 119 bpm and BP = 95/60 mmHg. Physical exam is significant for seat belt abrasions over chest and lower abdomen.

**Sonographic Findings:** With the 3.5MHz abdominal transducer placed in the sagittal plane in the right upper quadrant, anterior axillary line, the normal interface between liver and right kidney is viewed in image (a). In image (b) a dark stripe of abdominal fluid (likely hemoperitoneum in the setting of abdominal trauma) is seen in the hepato-renal space, also known as Morrison’s Pouch.

**Presumptive diagnosis:** hemoperitoneum

**Significance:** In the setting of an unstable trauma patient, the finding of free abdominal fluid on the FAST exam is an indication to proceed directly to definitive surgical management.

Case II

**Liver**

**Kidney**

**Free Fluid In Morrison’s Pouch**

**Echogenic clot in lumen**

**9 cm**
**Case History:** 79 year-old man is found unresponsive at home. In the ED, vital signs were significant for a heart rate of 109 bpm and a blood pressure of 94/52. There is no evidence of trauma. No family was available to provide any medical history.

**Sonographic Findings:** With the 3.5MHz abdominal transducer placed in the transverse plane above the umbilicus, the above image shows an abdominal aorta with a transverse external diameter of 9.4 cm (normal aortic diameter < 3cm). Echogenic (‘white’ on ultrasound) clot is seen surrounding the anechoic (‘black’) aortic lumen.

**Presumptive diagnosis:** ruptured AAA

**Significance:** Ultrasound is a useful adjunct in the approach to the patient with shock of unknown etiology. Whether the cause is a ruptured AAA, a pulmonary embolus, cardiogenic shock, or cardiac tamponade ultrasound provides vital information rapidly and at the bedside.

---

**Case III**

![Image](image_url)

**Case History:** A 32 year-old women presents with epigastric pain and vomiting 1 hour after eating. She reports a similar episode of ‘food poisoning’ 3 weeks ago that resolved spontaneously. On physical exam, she is afebrile, and her abdomen is obese with slight epigastric tenderness. Otherwise, physical exam is unremarkable.

**Sonographic Findings:** With the 3.5MHz abdominal transducer placed in the sagittal plane in the right upper quadrant, image (a) shows a normal gallbladder (GB), with the common bile duct (CBD) as the structure above the portal vein (PV). In our patient, image (b), there is the presence of a large gallstone in the gallbladder. Acoustic shadowing may be seen posterior to the gallstone. The wall of the gallbladder is not thickened (less than 3mm) and there is no pericholecystic fluid. Sonographic Murphy’s sign, tenderness over the gallbladder with compression with the ultrasound transducer, is notably absent.

**Presumptive diagnosis:** Biliary colic.

**Significance:** Emergency ultrasound can be readily utilized to identify the spectrum of biliary disease, from biliary colic to acute cholecystitis.
Case IV

**Case History:** A 23-year-old woman presents with lower abdominal pain and slight vaginal bleeding for 2 days. Her last menstrual period was 6 weeks ago, but she reports a history of irregular menses. On physical exam, all vital signs are within normal, the abdomen is thin and soft, and pelvic exam is significant for a closed os, trace blood in the vaginal vault and no adnexal masses or tenderness. Urine pregnancy test is positive.

**Sonographic Findings:** Using a 7.5Mhz endovaginal probe in the sagittal orientation, image (a) demonstrates a uterus without evidence of an IUP. The presence of the endometrial stripe ensures to the image reviewer that the endometrium is adequately visualized. No free pelvic fluid is seen in the posterior cul-de-sac.

Image (b) demonstrates an intrauterine yolk sac, considered definitive proof of an IUP. This embryonic nutritive structure is first seen on transvaginal ultrasound at 5-6 weeks gestational age. On magnified imaging (c), fetal cardiac activity is demonstrated in the fetal pole adjacent to the yolk sac.

Image (d) from another patient shows a complex adnexal structure and free fluid in the pelvis – findings that are highly suspicious for an ectopic pregnancy.

**Presumptive diagnosis:**
Image (a): no definitive IUP
Image (b): IUP (no fetal heart)
Image (c): live IUP (positive fetal heart)
Image (d): high suspicion for ectopic pregnancy.

**Significance:** Emergency ultrasound in the first trimester of pregnancy allows the emergency physician to rapidly and accurately evaluate the patient at risk of ectopic pregnancy.12-14
Limitations of Emergency Ultrasound

The quality of the imaging and information gathered depends upon the experience of the sonographer. Studies have shown that with limited training (sometimes no more than one hour of instruction), emergency physicians attain accuracy in placing ultrasound-guided central lines9,22,23, identifying hemoperitoneum24 and other pathology. Physicians new to this technology understand the difficulty in obtaining and interpreting quality ultrasound images.

Other challenges are financial and political: purchasing an ultrasound machine, financing machine maintenance, credentialing emergency department staff within the hospital, and obtaining the time and money for training. Although surmountable, all of these concerns may prove difficult to overcome.

Conclusion

Ultrasound performed by emergency physicians is rapidly becoming ‘standard of care’. With the recent mandatory inclusion of ultrasound training as part of the emergency medicine residency core curriculum25,26,27 and multiple studies showing the improvement in patient care28,29, it is a skill that all of us will need to eventually adopt.

The scope of emergency ultrasound is also developing. From accepted uses such as trauma to the less conventional role in estimating intracranial pressure30, there is no doubt that ultrasound is a rapid and safe diagnostic and procedural tool.
